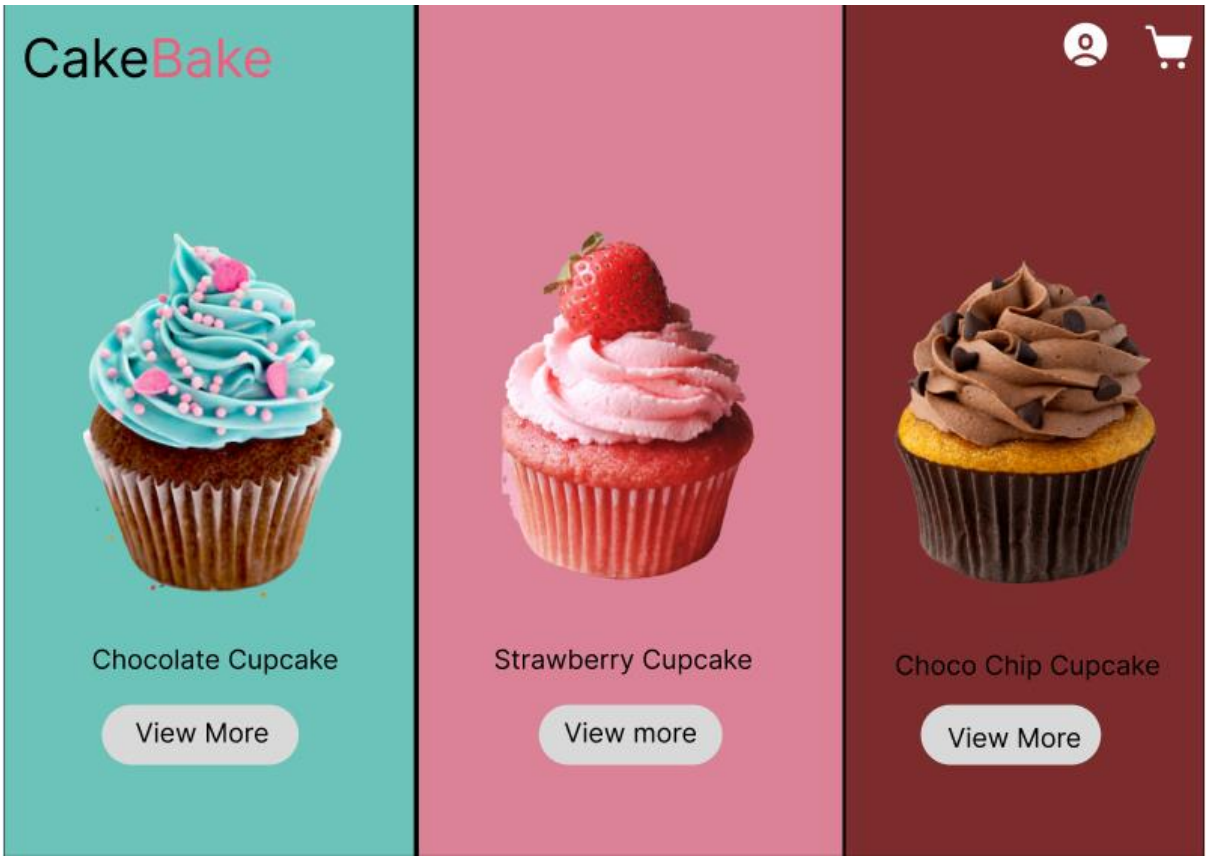
EXP.NO:01 **GOOD AND BAD DESIGN**

This experiment focuses on understanding the principles of good and bad design by analyzing various examples from everyday products, websites, and systems. The objective is to identify the characteristics that make a design effective or ineffective from a user's perspective

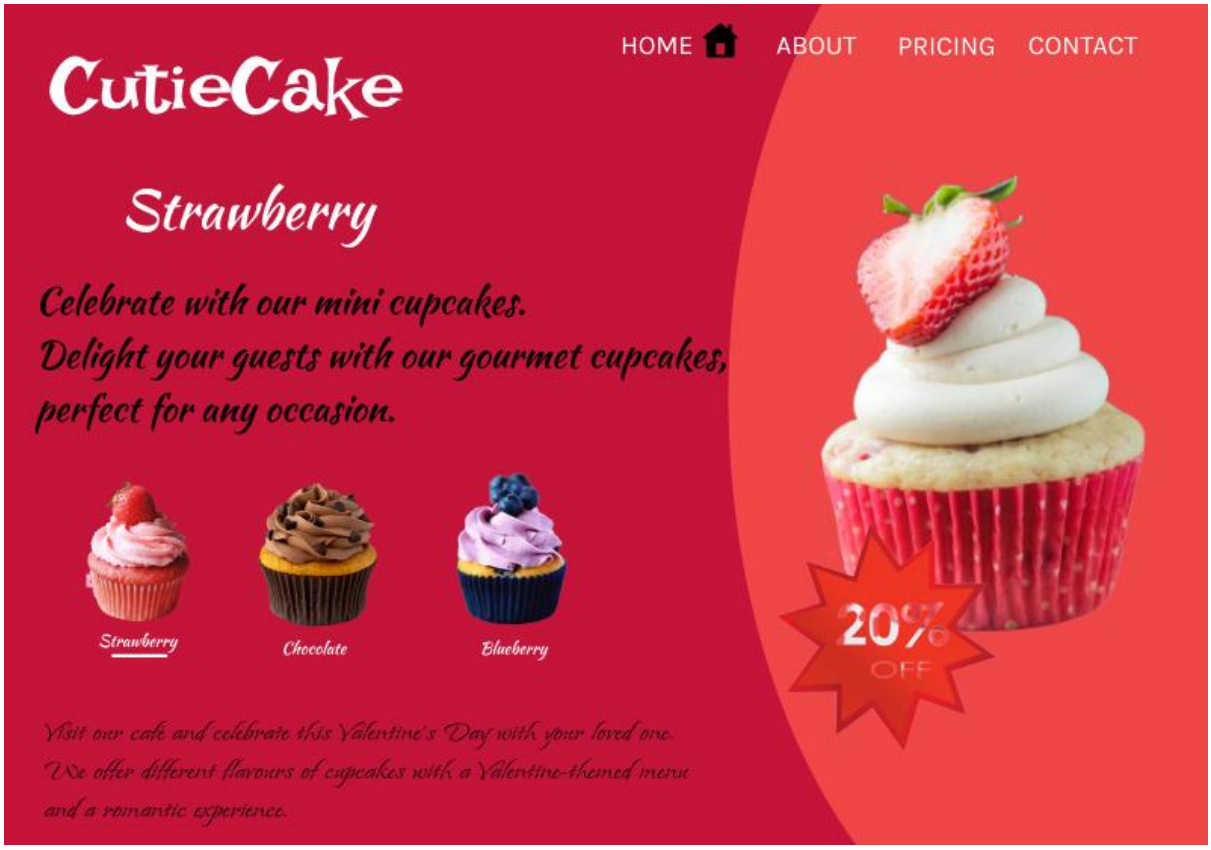
BAD DESIGN



Bad design, on the other hand, creates confusion and frustration for users. It lacks clarity, consistency, and usability. Poor navigation, overcrowded interfaces, unclear instructions, and inconsistent layouts are common signs of bad design. Such designs increase the chances of user errors, reduce efficiency, and negatively impact the user experience. Bad design often ignores user needs and fails to follow basic design principles.

Through this experiment, the differences between good and bad design are clearly understood. It highlights the importance of user-centered design and the role of usability in developing effective systems.

GOOD DESIGN



Good design refers to designs that are user-friendly, simple, intuitive, and efficient. It ensures that users can easily understand and interact with the system without confusion. Key features of good design include clarity, consistency, accessibility, and aesthetic appeal. A well-designed system minimizes user effort, reduces errors, and enhances the overall user experience. It follows established design principles such as proper alignment, contrast, balance, and usability.

Conclusion:

A good design improves usability, efficiency, and user satisfaction, while bad design leads to confusion and inefficiency. Therefore, following proper design principles is essential for creating successful and user-friendly systems.
